Population Projections 5

Scope and Methodology

Population projections for North Dakota are presented in this report by age and gender for the years 1990, 1995 and 2000. This report updates an earlier publication (see Rathge et al., 1985) released in 1985. These new figures reflect the downward trend in the state's population which started in the mid 1980s and has persisted. The projections were developed using a standard cohort-survival model. This approach differs from the economic-demographic simulation model used in previous versions. We shifted methodological techniques for two reasons. First, limited energy development activity occurred in the state since 1985, thus population movement was less dynamic. Second, trend data were available for county-specific migration patterns, thus the cohort-survival model was viewed as the most appropriate technique.

Cohort-Survival Model

A cohort-survival model is accepted as one of the most accurate projection techniques. Conceptually, the method applies a set of birth rates, death rates, and migration rates to a set of baseline population figures for a specific point in time to determine the population at a later point in time. To accomplish this, assumptions must be made about trends in births, deaths, and migration. These assumptions are addressed separately.

Birth Rates

The number of births projected to occur in each county was derived from age-specific fertility rates. These rates were based on an average of the total number of births in each age cohort of mothers for the years 1979, 1980, and 1981. The three-year average was used to control for year-to-year variations. Fertility rates were calculated for mothers between 14 to 45 years of age. Births occurring to mothers outside these ages were averaged into the top and bottom age cohorts. County-specific fertility rates were used in the model. It was assumed that these rates would continue throughout the projection period.

Death Rates

Rates of death in North Dakota are very similar among counties. Therefore, we used statewide rates for each county. The rates reflect age-and-gender specific mortality based on an average for the years 1979, 1980, and 1981. Once again, the three year average controlled for year-to-year fluctuations in deaths. The actual rates were calculated using a standard life table.

Migration Rates

Age-and gender-specific migration rates were calculated using a residual technique (see Shryock and Siegel, 1976). The two series of projections in this report reflect different migration rates. The first series uses age and gender-specific migration rates by county from 1970 to 1980 as a base. This base was adjusted to reflect overall county migration patterns from 1980 to 1988. It assumes that this migration trend will continue throughout the projection period. The second series uses the same base but adjusts the pattern to reflect overall county specific migration from 1987 to 1988. It also assumes that this trend will continue throughout the projection period.

Projection Series

Two series of projections are presented in this report. They represent different migration scenarios in that the assumptions regarding births and deaths are the same for the two series. Series I was developed by applying county specific net migration rates for the period 1980 to 1988 to the 1980 population base. This base population was segmented into 17 five-year age cohorts by gender with the last cohort representing the population above the age of 84. Baseline migration rates for each age and gender cohort were established using the trend from 1970 to 1980. These adjusted migration rates were assumed to mirror the trend in migration throughout the projection period. One should keep in mind that the annual net-migration rates for North Dakota counties changed dramatically during this period. For example, many counties had net in-migration during the early part of the decade. However, this trend reversed by 1984 with most counties showing net migration losses. By 1988, few counties showed net gains in migration. As a result, gains in the early 1980s offset losses which occurred during the later part of the decade. Thus, a net migration trend from 1980 to 1988 moderates the level of out-migration. Users interested in ascertaining what the state's population would look like if these moderated conditions were to continue over then next ten years should use Series I projections.

Series II projections portray a much different scenario. They were developed by adjusting the 1980 base population to one which aligned closely with the local review counts from the 1990 Census. The 1987 to 1988 county specific net-migration rates were then applied to this adjusted base and assumed to continue throughout the projection period. Since this annual rate reflects a general trend of out-migration, this series projects a much heavier population loss then the first series.

Limitations

Population projections are mathematical calculations which indicate the population that would result given that specific assumptions would persist throughout the projection period. Although information depicting North Dakota's resident population is relatively accurate, our ability to forecast changes in any socioeconomic or demographic process which may alter current population trends is tenuous at best. It is wise, therefore, to utilize these projections with caution. They should not be viewed as the sole element in planning or decision making, rather as only one tool in the process.
